ANTIOXIDANTS AND OTHER NUTRIENTS DO NOT INTERFERE WITH CHEMOTHERAPY OR RADIATION THERAPY AND CAN INCREASE KILL AND INCREASE SURVIVAL, PART 1

Charles B. Simone II, MD; Nicole L. Simone, MD; Victoria Simone, RN; Charles B. Simone, MD

Purpose • Some in the oncology community contend that patients undergoing chemotherapy and/or radiation therapy should not use food supplement antioxidants and other nutrients. Oncologists at an influential oncology institution contended that antioxidants interfere with radiation and some chemotherapies because those modalities kill by generating free radicals that are neutralized by antioxidants, and that folic acid interferes with methotrexate. This is despite the common use of amifostine and dexrazoxane, 2 prescription antioxidants, during chemotherapy and/or radiation therapy.

Design • To assess all evidence concerning antioxidant and other nutrients used concomitantly with chemotherapy and/or radiation therapy, the MEDLINE® and CANCERLIT® databases were searched from 1965 to November 2003 using the words *vitamins, antioxidants, chemotherapy,* and *radiation therapy*. Bibliographies of articles were searched. All studies reporting concomitant nutrient use with chemotherapy and/or radiation therapy (280 peer-reviewed articles including 62 in vitro and 218 in vivo) were indiscriminately included.

Results • Fifty human clinical randomized or observational trials have been conducted, involving 8,521 patients using beta-carotene; vitamins A, C, and E; selenium; cysteine; B vitamins; vitamin D_3; vitamin K_3; and glutathione as single agents or in combination.

Conclusions • Since the 1970s, 280 peer-reviewed in vitro and in vivo studies, including 50 human studies involving 8,521 patients, 5,081 of whom were given nutrients, have consistently shown that non-prescription antioxidants and other nutrients do not interfere with therapeutic modalities for cancer. Furthermore, they enhance the killing of therapeutic modalities for cancer, decrease their side effects, and protect normal tissue. In 15 human studies, 3,738 patients who took non-prescription antioxidants and other nutrients actually had increased survival. (*Altern Ther Health Med*. 2007;13(1):22-28.)

Charles B. Simone II, MD, and Nicole L. Simone, MD, are consulting physicians, Victoria Simone, RN, is a research nurse, and Charles B. Simone, MD, is a consulting physician and medical director, all at the Simone Protective Cancer Institute in Lawrenceville, NJ.

Editor's note: The following is part 1 of a 2-part article. Part 2 will appear in the March/April 2007 issue of Alternative Therapies in Health and Medicine.

Two of every 5 Americans will develop cancer, and the incidence of most cancers has increased annually since 1930.[1-5] In addition, since 1930, despite the use of radiation therapy, chemotherapy, immunotherapy, and improved surgical and diagnostic techniques, there has been limited improvement in cancer survival rates for most adult cancers.[1-5] Chemotherapy and radiation therapy, however, continue to have a large role in cancer treatment but produce great morbidity. Two prescription medicines, amifostine and dexrazoxane, both antioxidants, reduce cancer therapy side effects without interfering with antitumor killing. Amifostine (WR-2721) is an antioxidant analog of cysteamine that was discovered by the armed forces at Walter Reed Army Medical Center, Washington, DC, and became the first antioxidant agent to be approved by international regulatory agencies.[6] According to 29 studies, amifostine reduces side effects and increases response rates of chemotherapy and radiation therapy without interfering with their antitumor killing activity.[6-18] Twenty-one studies indicate that dexrazoxane (ICRF-187) protects the heart from adriamycin toxicity without interfering with the antitumor effect[19-22] by chelating iron that would otherwise form free radicals.[23-26]

Despite the common use of amifostine and dexrazoxane, and in direct opposition to clear scientific findings since the 1970s,

Editor's note: The following is part 2 of a 2-part article. Part 1 appeared in the Jan/Feb 2007 issue of Alternative Therapies in Health and Medicine *(*Altern Ther Health Med*. 2007;13(1):22-28).*

Two of every 5 Americans will develop cancer, and the incidence of most cancers has increased annually since 1930.[1-5] In addition, since 1930, despite the use of radiation therapy, chemotherapy, immunotherapy, and improved surgical and diagnostic techniques, there has been limited progress in cancer survival for most adult cancers.[1-5] Chemotherapy and radiation therapy, however, continue to have a large role in cancer treatment but produce great morbidity. Two prescription medicines, amifostine and dexrazoxane, both antioxidants, reduce cancer therapy side effects without interfering with antitumor killing.

A single, front-page interview in *The New York Times* in 1997, which was not based on published scientific work,[6] and a single research paper involving mice, along with a press release by its author in 1999,[7] led to the erroneous notion that vitamin C interferes with chemotherapy and radiation in humans. This notion soon applied to all antioxidants as physicians, patients, the media, the American Cancer Society,[8,9] and scores of websites took the same position without reviewing the scientific evidence. Methods have been presented in Part 1. Part 2 reviews data about antioxidant combinations, B vitamins, vitamins D_3 and K_3, and the glutathione-selenium complex. A summary and discussion are presented.

REVIEW OF STUDIES

Antioxidant Combinations

In an observational study, 58 children with various cancers were treated with chemotherapy appropriate for their site and total parenteral nutrition (TPN) that contained antioxidants, nutrients, fats, protein, glucose, and electrolytes. A 36% response rate was obtained for these patients, who otherwise would have been denied adequate chemotherapy because of fear of complications from malnutrition. Compared to historical controls, patients

in this study had few side effects and a higher response rate.[10]

In an observational study, 41 children with various cancers (Wilm's tumor, hepatic cancer, leukemia, lymphoma, primary bone cancer, and others) were treated with chemotherapy and radiation therapy appropriate for their site and TPN that contained antioxidants, nutrients, protein, fats, glucose, and electrolytes. Twenty-one children were able to continue their chemotherapy treatment at full dose without interruption while being administered TPN. Compared to historical controls, patients in this study had few side effects and a higher response rate.[11]

In another observational study, 18 patients with small cell lung cancer were treated with cyclophosphamide, doxorubicin HCL (adriamycin), vincristine chemotherapy, and/or irradiation at regular intervals. Their serum was analyzed for nutrient levels. In doses based on the serum analysis, all patients were given the following daily supplements of vitamins and minerals: 15,000-40,000 IU vitamin A; 10,000-20,000 IU beta-carotene; 300-800 IU vitamin E; 150-750 mg thiamin; 15-50 mg riboflavin; 200-1,140 mg pyridoxide; 0.03-1.60 mg vitamin B_{12}; 150-400 mg nicotinamide; 400-1,000 IU vitamin D; 2,000-5,000 mg vitamin C; 50-300 mg calcium; 0.3-10 mg biotin. The administration of these vitamins and minerals during chemotherapy and/or irradiation prolonged survival, decreased side effects, and increased response rates when compared to historical controls in the literature of patients who received only chemotherapy and radiation without vitamins and minerals. In this study, patients who had increased survivals started antioxidants before treatment began.[12]

In an observational study of 32 patients with breast cancer that spread to axillary lymph nodes, patients were given conventional surgical and therapeutic treatments, as well as daily supplements of vitamin C (2,850 mg), vitamin E (2,500 IU), beta-carotene (32.5 IU), selenium (387 μg), essential fatty acids (1.2 g gamma linolenic acid and 3.5 g omega-3 fatty acids), and coenzyme Q10 (90 mg). Compared to patients who received conventional treatment only, this group had decreased rates of recurrence and increased quality of life, survival rates, and partial remission rates.[13]

In an observational study of 63 patients with oral squamous cell carcinoma, participants received inductive concomitant chemoradiotherapy with cobalt 60 (30Gy), peplomycin (38 mg), and 5-fluorouracil (3,500 mg), as well as daily doses of vitamin C (500 mg), vitamin E (200 IU), and glutathione (200 mg). Patients were also given azelastine, an antihistamine (2 mg/day). Patients experienced an increased response rate and a greater reduction in the severity of side effects from the chemoradiotherapy.[14]

In another study, 41 patients with unresectable or metastatic gastric cancer were randomized to receive supportive care or 5-fluorouracil (1,500 mg/m^2) and methotrexate (1,500 mg/m^2) on day 1, leukovorin rescue (30 mg every 6 hours for 48 hours) and epirubicin (60 mg/m^2) on day 15. All patients received vitamins A (9,000 IU) and E (210 mg) daily. Compared to historical controls treated with the same chemotherapy regimen, the administration of vitamins A and E increased patient survival slightly.[15]

In an observational study of 17 patients with squamous cell carcinoma of the upper aerodigestive tract, patients were treated with radiotherapy, antioxidants, and beta-alanine, an amino acid. They were followed for 63 months and found to have decreased side effects from radiotherapy, improved physical comfort, and increased survival compared to a reference population of patients with squamous cell carcinoma of the upper aerodigestive tract.[16]

In an observational study of 20 patients with various metastatic cancers (lymphoma, leukemia, Hodgkin's, multiple myeloma, sarcoma, lung, pancreatic, kidney, colon, melanoma, and breast), patients were treated with chemotherapy appropriate for their site. During and after chemotherapy, they were given 4 doses a day each of vitamin A (100,000 IU), vitamin E (800 IU), and vitamin C (2 g). The complete and partial response rate (greater than 50% reduction in mass) was 75%—significantly higher than the expected 40%. Side effects were also decreased with this vitamin regimen.[17]

In an observational study of 10 patients with various cancers (lymphoma, breast, lung, esophageal, head and neck, colon, and choriocarcinoma), participants were treated with chemotherapy appropriate for their site. After the chemotherapy produced profound side effects (eg, nausea; vomiting; depression of neutrophils, platelets, red cells), nutrients, including selenium and vitamins A, C, and E, were added to the treatment program. Absolute neutrophil and platelet counts were significantly higher when the nutrients were added, allowing for decreased side effects.[18]

In a randomized study of 24 patients with various cancers who received either chemotherapy (14 patients) or radiation therapy (10 patients), participants were randomized to receive placebo or antioxidants (N-acetylcysteine and vitamins E and C). As determined by ejection fraction, antioxidants protected the heart from the damage of chemotherapy and radiation therapy. The left ventricular ejection fraction dropped significantly in patients receiving placebo (radiation therapy: 67% down to 56%; chemotherapy: 67% down to 60%), whereas patients receiving antioxidants showed limited decreases in the ejection fraction (radiation therapy: 63% down to 61%; chemotherapy: 67% down to 64%).[19]

B Vitamins

In a randomized study of 25 patients with locally advanced breast cancer, head and neck cancers, or melanoma, patients were treated with radiation and hyperthermia. They were randomized to receive nicotinamide (up to 9 g) by mouth 1 hour before treatments in an attempt to increase blood flow around the tumor. Nicotinamide decreased side effects and produced a complete response in 72% and an overall response rate of 88% (complete and partial responses). Those who achieved a complete response (72%) did not have a recurrence at the treatment site for as long as the patients were followed (time not defined by study authors).[20]

In a randomized study of 6,300 patients with gynecological and breast cancers treated from 1960 to 1988 with chemotherapy appropriate for their site, patients were randomized to receive pyridoxine (300 mg per day) during radiation, as the author had documented that radiation decreased serum nutrient levels of pyridoxine and other nutrients. Those who received pyridoxine had a 15% higher 5-year survival, fewer side effects, and a higher response rate.[21]

In another study, 248 patients with stage III or stage IV ovarian epithelial cancer were randomized to receive cisplatin (37.5 mg/m^2 or 75 mg/m^2 intravenously on day 1) and hexamethylmelamine (200 mg/m^2 orally on days 8-21) with or without oral pyridoxine (300 mg/m^2) administration on days 1-21. Pyridoxine administration significantly reduced neurotoxicity.[22]

Vitamin D_3

In an observational study, 44 patients with high-risk primary myelodysplastic syndromes and an excess of marrow blasts were treated with a combination of low-dose cytosine arabinoside (Ara-C; 10 mg/m^2), retinoic acid (20 mg/m^2/d), and vitamin D_3 (0.75 mg/d) until relapse or death. A matched control group of 44 additional patients was given supportive therapy only. The intervention group had a higher overall response rate (50% compared to 20%) and a significantly better survival rate than the control group and treated historical controls from other series (40% compared to 10%, *P*<.0001).[23]

Vitamin K_3

In an observational study, 51 patients with various refractory solid tumors were treated with a 48-hour continuous intravenous infusion of vitamin K_3 (menadione; 1.0 to 3 g/m^2), followed by a bolus of mitomycin C (5-20 mg/m^2). In this study, menadione decreased side effects and increased the response rate.[24]

In another observational study, 14 patients with various advanced cancers (7 patients with chronic lymphocytic leukemia, and 1 patient each with lymphoma, acute lymphocytic leukemia, acute myelogenous leukemia, multiple myeloma, breast, ovary, and small cell lung cancer) were treated with 18 courses of vitamin K_3 (40-3,200 mg/m^2 per course administered over 1 to 4 days) and various combinations of cytotoxic drugs appropriate for their site. The cytotoxic agents included carmustine, cyclophosphamide, dexamethasone, doxorubicin, melphalan, nitrogen mustard, platinum, vinblastine, and vincristine. Menadione increased the response rate and decreased the side effects of chemotherapy, possibly by altering drug-resistance profiles.[25]

Glutathione

In an observational study of 50 consecutive patients with untreated stage III or stage IV ovarian cancer, patients were treated with 2 cycles of cisplatin (40 mg/m^2), carboplatin (60 mg/m^2), and glutathione (2,500 mg before chemotherapy), followed by debulking surgery where possible and 3 more cycles of chemotherapy and glutathione. Fifty-four percent of patients had a complete response, there were fewer side effects, and survival was better than expected (median survival >48 months).[26]

In another observational study, 12 patients with stage III ovarian cancer and 23 patients with localized disease at high risk for recurrence were treated for 3 weeks with cisplatin (90 mg/m^2 intravenously over 30 minutes) and cyclophosphamide (600 mg/m^2 intravenously). Glutathione (5 g in 200 mL of normal saline) was administered 15 minutes before cisplatin treatments by short-term fusion. In addition to decreasing cisplatin-associated toxicity, glutathione optimized efficacy of cisplatin treatment. At the conclusion of the treatments, all but 2 of the stage III patients had complete pathological responses, and all of the high-risk patients remained disease-free. There was no renal impairment or neurotoxicity.[27]

In a randomized study, 50 patients with advanced gastric cancer were treated with a weekly cisplatin-based regimen. Patients in the intervention group received 1.5 g/m^2 of glutathione in 100 mL of normal saline 15 minutes before cisplatin treatment and 600 mg of glutathione by intramuscular injection on days 2 and 5. After 15 weeks of treatment, only 4 of the 24 patients randomized to receive glutathione suffered from neurotoxicity, as compared to 16 of 18 patients in the placebo (normal saline) group. Glutathione also reduced hemotransfusion requirements (62% in the intervention group vs 32% in the control group). Although glutathione reduced treatment toxicity, it did not reduce the clinical activity of the cisplatin-based chemotherapy. In fact, patients receiving glutathione had a higher response rate (76%) than patients in the placebo group (52%).[28]

In an observational study, 11 previously untreated patients with metastatic colorectal cancer were given 5-fluorouracil (750 mg/m^2 on days 1-5) and cisplatin (40 mg/m^2 on days 6-8) every 4 weeks. Glutathione (2.5 g) was administered intravenously before each cisplatin infusion. Side effects from treatment were reduced without altering the response rate.[29]

In another observational study, 79 patients with advanced stage III or stage IV ovarian cancer were treated with high-dose cisplatin (40 mg/m^2), glutathione (2,500 mg as a short-term infusion prior to cisplatin), and cyclophosphamide (600 mg/m^2). After a total of 345 courses, 57% of patients achieved complete clinical responses, and 25% had partial remissions (an 82% overall response rate). Toxicity of the regimen was moderate, and the severity of peripheral neurotoxicity and ototoxicity was less than has been reported with similar high-dose cisplatin regimens without glutathione administration.[30]

Forty patients with stage III or stage IV ovarian carcinoma in an observational study were treated with glutathione (1,500 mg/m^2) over 15 minutes before cisplatin (40 mg/m^2 days 1-4) and cyclophosphamide (600 mg/m^2 on day 4) treatments. Treatment was repeated every 3 to 4 weeks. After 5 courses of treatment, 62% of patients achieved complete clinical remission, and the overall response rate was 86%. Glutathione prevented renal impairment, allowed for an improved toleration to the high-dose cisplatin treatment, and increased the response rate of the treatment.[31]

In another observational study, 27 patients with bulky, operable cervical cancer (stage IB/II) were given 1 course of cisplatin (40 mg/m^2 for 5 consecutive days) with glutathione protection and bleomycin (15 mg on days 2, 8, and 9). One month later, 21 patients had objective responses that made surgery easier. There were also fewer side effects from treatment.[32]

In another observational study, 12 patients with either non-small cell lung cancer or pleural mesothelioma were given 2 courses of cisplatin (80 mg/m^2) by infusion every 3 to 4 weeks. Six of these patients were pretreated with glutathione (2.5 g intravenous-

ly) 15 minutes before cisplatin treatment. These patients had higher response rates and fewer side effects than patients who were not given glutathione protection.[33]

Twenty patients with advanced ovarian carcinoma were treated every 21 to 28 days with cisplatin (45 mg/m^2 intravenously on days 1 and 2), cyclophosphamide (900 mg/m^2 intravenously on day 2), and glutathione (2,500 mg intravenously over 15 minutes, before cisplatin treatment) in an observational study. Compared to patients with similar conditions who received similar treatments without glutathione, patients in this study had decreased nephrotoxicity and neurotoxicity. Furthermore, glutathione improved the efficacy of treatment in these patients, producing a pathological complete response rate of 55% and a median survival of 26.5 months. Five patients were still alive and disease-free at 35 months.[34]

Thirteen patients with various cancers (sarcomas, breast, renal, histiocytoma, and Schwannoma) underwent treatment every 4 weeks with cyclophosphamide (1 hour infusion in escalating doses from 1.2 to 1.6 g/m^2) and glutathione (administered intravenously in 2 divided doses of 2.5 g in 100 mL normal saline 15 minutes before and 30 minutes after cyclophosphamide treatment) in this observational study. Glutathione protected against cyclophosphamide-induced urotoxicity and bladder damage without interfering with the efficacy of the cyclophosphamide.[35]

In another observational study, 15 patients with ovarian cancer and 1 with unknown adenocarcinoma were treated for a maximum of 5 consecutive courses with cisplatin (90 mg/m^2) and cyclophosphamide (600 mg/m^2) with or without glutathione (1,500 mg/m^2) before each cisplatin treatment. Glutathione reduced the severity of myelosuppression and nephrotoxicity without interfering with the efficacy of treatment.[36]

In a randomized study, 36 patients with advanced ovarian cancer were treated every 4 weeks with cisplatin (40 mg/m^2). Patients who were randomized to receive glutathione (1.5 g/m^2 given by infusion over 15 minutes before cisplatin treatment) experienced less ototoxicity and other side effects. There were no differences in response rates between the groups.[37]

In an observational study by Plaxe et al, 16 patients with various advanced cancers in a phase I trial were given escalating doses of cisplatin (up to 125 mg/m^2) and glutathione (3 g/m^2 fixed dose) every 21 days. Evaluation after 44 cycles of treatment indicated that glutathione reduced nephrotoxicity, ototoxicity, and other side effects of cisplatin. Glutathione also allowed an increase to 175% of cisplatin dose intensity.[38]

In a large observational study by Smyth et al, 151 patients with ovarian cancer were divided into 2 groups. The intervention group was given cisplatin (100 mg/m^2) and glutathione (2.5 g before cisplatin), and the control group received only cisplatin at the same dose. Patients given glutathione had less toxicity from cisplatin and were better able to tolerate 6 cycles of treatment (58% compared to 39% of patients in the control group). Patients who received glutathione also had significant improvements in depression, emesis, peripheral neurotoxicity, hair loss, shortness of breath, and difficulty concentrating. Furthermore, patients in the glutathione group had better responses to treatment and improved quality of life.[39]

DISCUSSION

For patients undergoing chemotherapy and/or radiation therapy, physicians are comfortable with and commonly use 2 prescription antioxidants, amifostine and dexrazoxane, for their proven benefits of reducing side effects and increasing response rates without interfering with the antitumor killing of the therapy. However, physicians often tell patients not to take food supplement antioxidants and nutrients because 2 individuals from a trusted institution stated that nonprescription nutrients interfere with cancer therapies. Also, the authors of a recent randomized study concluded that "supplementation with antioxidants reduced the severity of treatment side effects but might compromise radiation therapy efficacy."[40] Of the 540 head and neck cancer patients treated with radiation, 273 were given 400 IU dl-alpha-tocopherol during radiation and for 3 years after, and 77 patients of these 273 were given 30 mg beta-carotene during radiation and thereafter ranging from a total of 21 days to 609 days. There were no data presented to support the issue of local recurrence that occurred in 103 patients, half of whom recurred during the first year. We don't know if the local recurrence was in the field of radiation, within 2 cm of the field, or outside the field altogether but in the vicinity. However, we do know there was no difference in survival as per their Kaplan-Meier curves. This paper, without objective supporting data, added to the controversy that antioxidants might compromise radiation efficacy.

Many of the food supplement nutrients used in the above studies are antioxidants, molecules that neutralize free radicals. Most cancer modalities exert their cancer killing effects by generating free radicals. Therefore, it would seem inconsistent that antioxidants could help cancer patients. However, since the 1970s, 280 peer-reviewed studies (62 in vitro and 218 in vivo) have been published (Figure), including 50 human clinical studies that used non-prescription antioxidants and other nutrients (8,521 patients, 5,081 of whom were given nutrients) and 50 studies on prescription antioxidants. These studies have consistently

Smyth (39)	Observational	151, ovarian	Glutathione	Cisplatin	None	Yes	Yes	Not

shown that non-prescription antioxidants and other nutrients do not interfere with cancer therapeutic modalities. In addition, non-prescription antioxidants and other nutrients enhance the killing of cancer therapeutic modalities, decrease their side effects, and protect normal tissues, and in 15 human studies, 3,738 patients actually had prolonged survival.

Cancer cells accumulate excessive amounts of antioxidants due to a loss of the homeostasis control mechanism for the uptake of these nutrients.[61] Normal cells do not have this membrane defect and do not accumulate large amounts of antioxidants. Accumulation of excessive antioxidants and nutrients in cancer cells can shut down the oxidative reactions necessary for generating energy. In addition, dietary antioxidants also produce biological effects on cancer cells that are not related to antioxidant action, as outlined here.

1. Antioxidants increase cancer cell differentiation and/or apoptosis, and growth inhibition.[62,63]
   a. Antioxidants inhibit gene expression and/or activity of p53 mutant, c-myc, H-ras, Bcl_2, c-neu, c-$erbB_2$, vascular endothelial growth factor (VEGF), phosphotyrosine kinase, and protein kinase C.
   b. Antioxidants enhance gene expression and/or activity of p53 wild-type, p21, c-fos, c-jun, HSP70, HSP90, connexin, transforming growth factor beta (TGFb), mitogen-activated protein (MAP) kinase, caspase, and cyclin A and D and their kinases.
2. Antioxidants selectively inhibit repair of radiation damage of cancer cells but protect normal cells when antioxidants are used before, during, and after radiation—there are no published studies that show antioxidants protect cancer cells against radiation.[64]
3. Vitamin E reduces the expression of VEGF and thus acts as an anti-angiogenic factor.

With higher levels of intracellular accumulation of nutrients by cancer cells, more of these cellular alterations occur. These changes can lead to higher rates of cancer cell death and reduced rates of cell proliferation and induction of differentiation. These acquired changes of cancer cells that result from high doses of nutrients apparently override any protective action that antioxidants have against free radical damage on cancer cells and account for what is demonstrated in the international literature about this subject. Non-prescription antioxidants and other nutrients do not interfere with cancer therapeutic modalities, enhance their killing capabilities, decrease their side effects, or protect normal tissues, and in 15 human studies, 3,738 patients actually had prolonged survival. Antioxidant and other nutrient food supplements are safe and can help to enhance cancer patient care.

many patients have been told not to use food supplement antioxidants and other nutrients while undergoing chemotherapy and/or radiation therapy because there is an erroneous but seemingly logical belief that antioxidants interfere with radiation and some chemotherapies because those modalities kill by generating free radicals that are neutralized by antioxidants, and another erroneous belief that folic acid interferes with methotrexate.[27-32]

In an article that appeared on the front page of *The New York Times* on October 26, 1997, Larry Norton, MD, of Memorial Sloan Kettering Cancer Center, New York, was quoted as saying, "Research at [Memorial Sloan Kettering] showed that large doses of vitamin C could blunt the beneficial effects of chemotherapy for breast cancer. . . . It is also known that folic acid can negate the effects of methotrexate, a drug used to treat cancer."[27] The research referred to was finally published almost 2 years later and demonstrated only the mechanism by which cancer cells obtain vitamin C and that more vitamin C was found in mice cancer cells compared to normal mice cells.[29] However, the senior author of that paper stated in a news release on the day of publication (September 15, 1999), "It's possible that taking large amounts of vitamin C could interfere with the effects of chemotherapy or even radiation therapy."[30] So a single interview in *The New York Times* in 1997 that was not based on published scientific work and a single research paper involving mice, along with a press release by its author in 1999, led to the erroneous notion that vitamin C interferes with chemotherapy and radiation in humans. This notion soon applied to all antioxidants as physicians, patients, the media, the American Cancer Society,[31,32] and scores of websites took the same position without reviewing the scientific evidence.

This 2-part article presents the scientific data that antioxidants do not interfere with chemotherapy and/or radiation therapy. Furthermore, it is not folic acid that interferes with the action of methotrexate, but rather folinic acid, a prescription drug that is neither a vitamin nor an antioxidant.[33-35] This article reviews data about vitamin A, beta-carotene, and vitamin E. Part 2 will review data about antioxidant combinations, B vitamins, vitamins D_3 and K_3, and the glutathione-selenium complex.

METHODS

MEDLINE® and CANCERLIT® searches were done using key words: vitamins, antioxidants, chemotherapy, and radiation therapy. All studies reporting food supplement nutrients used concomitantly with chemotherapy and/or radiation therapy were indiscriminately included; however, in cases in which an author had published his or her findings in multiple sources, only the most recently published paper was used as it usually contained the greatest number of patients.

BACKGROUND

Radiation and certain chemotherapies produce cellular kill by generating free radicals; antioxidants neutralize free radicals and the oxidative reactions that are caused by free radicals (Table 1).

Other nutrients are included in this review. B vitamins enhance the immune system and protect normal cells from the harm of radiation and other destructive mechanisms. Glutathione peroxidase, a selenium-containing antioxidant enzyme complex, protects the cell from free-radical injury. Glutathione peroxidase is easier to measure than selenium and has the advantage of assessing only biologically active selenium. Vitamin A and retinoids have anti-cancer effects, repair normal cells, and modulate the growth and differentiation of malignant cells. Vitamin D_3 inhibits cancer cell proliferation and replication, induces differentiation of leukemia cells, inhibits the oncogene c-*myc*, and enhances the immune system. Vitamin K_3 (menadione) inhibits cell growth, cell proliferation, DNA synthesis, and the cell cycle. Vitamin K_3 acts on apoptosis through expression of c-*myc* and c-*fos* proto-oncogenes and lowers intracellular pools of reduced glutathione.

TABLE 1 Agents That Generate or Neutralize Free Radicals

Generate Free Radicals	Antioxidants (Neutralize Free Radicals)
Alkylating Agents	Amifostine
Alkyl sulfonate—busulfan	Carotenoids—beta-carotene, lutein, lycopene
Ethylenimine derivative—thiotepa	Coenzyme Q10
Metal salt—cisplatin, carboplatin	Dexrazoxane
Nitrogen nustard—chlorambucil, estramustine, cyclophosphamide, ifosfamide, melphalan	Glutathione-selenium complex
Nitrosourea—carmustine	N-acetyl cysteine
Triazine—dacarbazine	Selenium
	Vitamin C
Natural Products	Vitamin E
Antibiotic—bleomycin, dactinomycin, daunorubicin, doxorubicin (adriamycin), idarubicin, mithramycin, mitomycin, mitoxantrone	
Podophyllum derivative—etoposide, teniposide	
Other—procarbazine	
Radiation—all forms	

Effects of Chemotherapy and Radiation Therapy on Serum Nutrient Levels

Cancer patients suffer from caloric and nutritional malnutrition and have vitamin deficiencies, particularly of folic acid, vitamin C, pyridoxine, and other nutrients because of poor nutrition and treatment.[38] Chemotherapy and radiation therapy reduce serum levels of antioxidant vitamins and minerals due to lipid peroxidation and thus produce higher levels of oxidative stress.[36-66] Iron could be the intermediate cause of this oxidative stress.[20-23] Therefore, supplemental iron should not be recommended to cancer patients who have anemia unless it is an iron-deficiency anemia.

Early Studies

Five early studies showed that N-acetyl cysteine, an antioxidant, protects the heart from the cardiac toxicity of adriamycin without interfering with the tumor-killing capability of adriamycin.[67] Seven cellular studies,[68-70] 22 animal studies,[71-75] and human studies[76-78] have demonstrated that vitamins A, E, C, and K, as well as beta-carotene and selenium—as single agents or in combination—all protect against the toxicity of adriamycin and actually enhance its cancer-killing effects.

Cellular and Animal Studies

Fifty-one cellular[79-88] and 81 animal studies[89-110] using nutrients that include vitamins A, B_6, B_{12}, C, D, E, and K, beta-carotene, other retinoids, selenium, or cysteine as single agents or in combination given concomitantly with chemotherapy, radiation, or combinations of these modalities show the same effect—no interference, increased protection of normal tissues, increased tumor killing, and, in some studies, increased animal survival.

Observational Versus Randomized Clinical Studies

Compared to randomized studies, observational studies are less costly, can be done more quickly, and have a broader range of patients. Observational studies provide valid information and virtually the same results as randomized studies, a finding that differs from previous conclusions.[111,112] Furthermore, "Observational studies do not overestimate the magnitude of the effects of treatment compared with those in randomized trials on the same topic."[113(p1887)] In this 2-part article, we will summarize 50 human studies, 36 observational and 14 randomized, that reported concomitant nutrient use with chemotherapy and/or radiation therapy.

Review of Human Studies

Fifty human studies, involving 8,521 patients, have been conducted using single or multiple nutrients in combination with systemic treatment and/or radiation treatment and demonstrate that nutrients do not interfere with treatment. In fact, 47 of these 50 studies indicated that nutrients decrease side effects of treatment, and the other 3 studies showed no difference. In addition, many of the studies reported that nutrients produce higher response rates and higher survival rates when administered concomitantly with chemotherapy and/or radiation therapy. This part of the 2-part article reviews data about vitamin A, beta-carotene, and vitamin E.[114-130]

VITAMIN A (RETINYL PALMITATE)

In a randomized study of 100 postmenopausal patients with metastatic breast carcinoma undergoing chemotherapy (cyclophosphamide, 5-fluorouracil, bleomycin, adriamycin, mitomycin), patients were given daily doses of vitamin A (350,000-500,000 IU, according to body weight). Vitamin A—which many people erroneously believe is an antioxidant—significantly increased the complete response rate, duration of response, and projected survival.[114]

In an observational study of 275 patients with head and neck cancer, patients were treated with 5-fluorouracil and cobalt-60 radiation, as well as vitamin A. Vitamin A enhanced the cellular sensitivity to irradiation, increased treatment response rate, and lowered toxic side effects.[115]

In a randomized study of 153 patients with chronic myelogenous leukemia (CML), patients were randomized to receive pulse oral busulfan with or without the daily administration of oral vitamin A (50,000 IU). Patients receiving only busulfan had a shorter survival, with a 42% greater risk of death. In addition to increasing survival, vitamin A decreased side effects and increased treatment response rate.[116]

In an observational study of 40 patients with stage IIIB or stage IV non-small cell lung cancer, patients were treated with cisplatin (120 mg/m^2 divided into 5 days), vindesine (3 mg/m^2 on days 1 and 5), 5-flourouracil (500 mg/m^2 on days 1 and 5), beta-interferon (1 million IU 3 times a week), and retinyl palmitate (50,000 IU twice a day). Vitamin A produced fewer side effects, a higher response rate, and increased survival compared to historical controls.[117]

In an observational study, 23 patients with unresectable or recurrent advanced oral cavity cancer were treated with 5-flourouracil (1,000 mg/m^2) and cisplatin (20 mg/m^2) for 5 days. Vitamin A (15,000 IU twice a day) was also given throughout the treatment. Vitamin A decreased side effects, increased response rate, and slightly increased survival.[118]

In an observational study of 36 patients with stage IV breast cancer, patients were treated with cyclophosphamide, 5-flourouracil, 4-epidoxorubicin, vincristine, and prednisone every 3 weeks for 6 courses, followed by 2 courses of methotrexate, mitomycin-C, and mitoxantrone. Treatment continued with tamoxifen and vitamin A. Sixty-four percent of patients had a clinical response, 19% had stable disease, and side effects were minimal. Median overall survival was 32 months. These results compare favorably with historical controls.[119]

In an observational study of 22 patients with unresectable and/or metastatic pancreatic cancer, patients were treated with folinic acid (200 mg/m^2), 5-flourouracil (370 mg/m^2), epirubicin (60 mg/m^2), mitomycin-C (10 mg/m^2), interferon (1 million IU/m^2 3 times a week), and vitamin A (50,000 IU twice a day). Response rates and survival were similar to historical controls.[120]

In an observational study of 49 patients with metastatic breast cancer, 33 were treated with tamoxifen (30 mg/d), interferon (1 million IU 3 times a week), and vitamin A (15,000 IU twice a day). Sixteen patients were treated with tamoxifen (30 mg/d), interferon (3 million IU 3 times a week), and vitamin A (50,000 IU twice a day). There was no statistically significant difference in the response rate, response duration, or survival in the 2 groups treated with different dose levels of vitamin A and interferon. Compared to the Surveillance, Epidemiology, and End Results (SEER) Program data of the National Cancer Institute, however, these patients had a higher response rate and longer survival with fewer side effects.[121]

BETA-CAROTENE

In a randomized study of 20 patients with advanced squamous carcinoma of the mouth, patients were given 60 Gy cobalt radiation therapy in 30 fractions. The week before and after radiation, and also during the third and sixth weeks of radiation, patients were given synchronous injections of chemotherapy consisting of vincristine (2 mg), methotrexate (200 mg), and bleomycin (30 mg). Patients were randomized to receive supplemental beta-carotene (250 mg for days 1-21; 75 mg daily thereafter). No toxic side effects of beta-carotene were observed. Patients who received supplemental beta-carotene had less severe acute mucosal reactions.[122]

In an observational study of 15 patients treated with chemotherapy for various advanced cancers, patients were given chemotherapy/radiation therapy and beta-carotene. Beta-carotene decreased side effects and allowed for a longer than expected disease-free interval in all surviving patients.[123]

VITAMIN E (ALPHA-TOCOPHEROL)

In an observational study of 66 patients with transfusion-dependent myelodysplastic syndrome, patients received either high-dose 13-cis-retinoic acid only or high-dose 13-cis-retinoic acid with alpha-tocopherol. Patients who received alpha-tocopherol had decreased measures of skin and constitutional toxicities and were able to achieve longer treatment continuation with 13-cis-retinoic acid. As a result, fewer of these patients experienced progression to acute leukemia (28%) when compared to patients who received 13-cis-retinoic acid only (60%). A 2-fold increase in median survival also was observed in the group treated with vitamin E.[124]

In an observational study of 39 patients with head and neck, skin, or lung cancer, study participants were treated with high-dose 13-cis-retinoic acid (100 mg/m^2 orally per day) and alpha-tocopherol administered in escalating dose schedules of 800, 1200, 1600, and 2000 IU per day for each subsequent 4-week treatment cycle. Over a 3-month period, patients experienced fewer grade 2 and grade 3 toxicities from high-dose 13-cis-retinoic acid without altering its plasma concentration.[125]

In an observational study of 17 patients with myelodysplasia, patients were treated with all-trans-retinoic acid (45 mg/m^2 in 2 divided doses), granulocyte colony-stimulating factor (started at 1 microgram/kg per day), erythropoietin (5,000 IU per day starting on day 2), and vitamin E (400 IU per day). Vitamin E reduced the toxicity and increased the response rate without affecting the performance of all-trans-retinoic acid.[126]

In an observational study involving 1 patient, the patient developed a skin carcinoma in a chest wall scar from having a mastectomy and radiation therapy 17 years earlier. After surgical excision of the carcinoma, she was treated with radiation therapy to the site. She also was given a vasodilator (pentoxifylline 1,200 mg/d) and vitamin E (400 IU per day) in an attempt to reduce the new scar formation. The authors concluded that vitamin E decreased the side effects of radiation, and the skin condition began to improve by the fourth month.[127]

In an observational study of 21 patients with metastatic breast cancer, patients had endomyocardial biopsies and were given alpha-tocopherol orally at 2 g/m^2 daily starting 7 days before cyclophosphamide, adriamycin, and 5-fluorouracil administration. Vitamin E did not compromise the antitumor activity of the chemotherapy. Fifteen of 21 achieved an objective response—similar to the authors' previous experience. Vitamin E allowed for an additional 100 mg/m^2 of adriamycin to be given, but the authors stated that vitamin E did not protect the heart.[45]

In a randomized study of 12 patients with metatstatic breast cancer, patients were treated with doxorubicin as an intravenous bolus infusion (60 mg/m^2), and 6 were randomized to receive 200 mg alpha-tocopherol given intramuscularly 6 hours before infusion and 60 mg nifedipine given orally each day for 2 days before treatment. A higher response rate was achieved and cardiac toxicity was prevented in those who received vitamin E and nifedipine.[46]

In a randomized study of 20 patients with acute myelogenous leukemia, patients were given vitamin E daily and treated with induction chemotherapy (10 patients) and intensive chemotherapy followed by bone marrow transplantation (10 patients). Vitamin E increased treatment response rate and prevented mucositis—an inflammatory response of the oral cavity caused by radiation therapy—especially during induction therapy for acute myelogenous leukemia.[128]

In a randomized study of 18 patients with various cancers, patients received chemotherapy appropriate for their cancer site and were randomized to receive either placebo oil or topical vitamin E (400 IU/cc) to control mucositis. For the 16 patients with head and neck cancer, 5-fluorouracil (1,000 mg/m^2 as a continuous infusion for 5 days) and cisplatin (100 mg/m^2 on day 2) were given. For the patient with hepatocellular carcinoma, doxorubicin (45 mg/m^2 every 3 weeks) was given. The patient with acute myelogenous leukemia (AML) received Ara-C (100 mg/m^2/d for 7 days) and doxorubicin (45 mg/m^2 on days 1-3). Oral mucositis lesions were observed daily before and 5 days after the application of either vitamin E or placebo oil. Vitamin E prevented chemotherapy-induced mucositis. In fact, whereas only 1 of 9 patients receiving placebo achieved complete resolution of their oral lesion, 6 of 9 patients receiving vitamin E achieved complete resolution.[129]

In a randomized study of 16 patients with various cancers, all participants were treated with a regimen containing adriamycin appropriate for the cancer site. Seven were randomized to receive 1,800 IU tocopherol daily starting 24 hours before adriamycin administration and continuing for at least 1 week after adriamycin administration. Vitamin E did not interfere with chemotherapy but also did not protect against cardiac toxicity.[47]

Sixteen evaluable cancer patients in an observational study of 18 patients receiving adriamycin were given dl-alpha-tocopherol acetate (1,600 IU a day) to determine whether vitamin E would protect against alopecia (hair loss), which occurs in virtually all patients receiving adriamycin. Sixty-nine percent of patients given adriamycin and vitamin E did not have alopecia.

Furthermore, a correlation was found between the time vitamin E was taken and the degree of alopecia. Most patients who began taking tocopherol more than 72 hours before chemotherapy treatment did not have alopecia.[130]

SUMMARY

These studies show that vitamin A, beta-carotene, and vitamin E do not interfere with and actually can enhance the killing capabilities of therapeutic modalities for cancer, decrease their side effects, protect normal tissues, and, in some studies, prolong survival. Part 2 will review antioxidant combinations, B vitamins, vitamins D_3 and K_3, and the glutathione-selenium complex. A summary and discussion will then be presented.
